# Bias-Variance Tradeoff

# Bias–Variance Decomposition of Error

---

- Consider simple regression problem  $f: X \rightarrow T$

$$t = f(x) = g(x) + \varepsilon$$

Collect some data, and learn a function  $h(x)$

What are sources of prediction error?

# Bias-Variance Tradeoff – Intuition

---

- Model too “simple” ! does not fit the data well
  - A biased solution
- Model too complex! small changes to the data, solution changes a lot
  - A high-variance solution

# (Squared) Bias of learner

---

- Given dataset  $D$  with  $m$  samples, learn function  $h(x)$
- If you sample a different datasets, you will learn different  $h(x)$
- **Expected hypothesis:**  $E_D[h(x)]$
- **Bias:** difference between what you expect to learn and truth
  - Measures how well you expect to represent true solution
  - Decreases with more complex model

$$bias^2 = \int_x \{E_D[h(x)] - g(x)\}^2 p(x) dx$$

# Variance of learner

---

- Given a dataset  $D$  with  $m$  samples, you learn function  $h(x)$
- If you sample a different datasets, you will learn different  $h(x)$
- **Variance:** difference between what you expect to learn and what you learn from a particular dataset
  - Measures how sensitive learner is to specific dataset
  - Decreases with simpler model

$$\bar{h}(x) = E_D[h(x)]$$

$$variance = \int E_D[(h(x) - \bar{h}(x))^2]p(x)dx$$

# Bias-Variance Tradeoff

---

- Choice of hypothesis class introduces learning bias
  - More complex hypothesis class  $\rightarrow$  less bias
  - More complex hypothesis class  $\rightarrow$  more variance

# Sources of Error 1 – Noise

---

- What if we have perfect learner, infinite data?
  - If our learning solution  $h(x)$  satisfies  $h(x)=g(x)$
  - Still have remaining, unavoidable error of  $\sigma^2$  due to noise  $\varepsilon$

$$error(h) = \int_x \int_t (h(x) - t)^2 p(f(x) = t | x) p(x) dt dx$$

## Sources of Error 2 – Finite Data

---

- What if we have **imperfect** learner, or only  $m$  training examples?
- What is our expected squared error per example?
  - Expectation taken over random training sets  $D$  of size  $m$ , drawn from distribution  $P(X,T)$

$$E_D \left[ \int_x \int_t \{h(x) - t\}^2 p(f(x) = t|x) p(x) dt dx \right]$$

# Bias–Variance Decomposition of Error

---

Then expected sq error over fixed size training sets  $D$  drawn from  $P(X,T)$  can be expressed as sum of three components:

$$E_D \left[ \int_x \int_t (h(x) - t)^2 p(t|x) p(x) dt dx \right] \\ = \text{unavoidableError} + \text{bias}^2 + \text{variance}$$

Where:

$$\text{unavoidableError} = \sigma^2$$

$$\text{bias}^2 = \int (E_D[h(x)] - g(x))^2 p(x) dx$$

$$\bar{h}(x) = E_D[h(x)]$$

$$\text{variance} = \int E_D[(h(x) - \bar{h}(x))^2] p(x) dx$$
